Proof.

The Descartes Equation

Proof.

First, we solve for d from the Descartes Equation to find that

The Descartes Equation

Proof.

First, we solve for d from the Descartes Equation to find that

$$2(a^2 + b^2 + c^2 + d^2) - (a + b + c + d)^2 = 0$$

$$d^2 - 2d(a + b + c) + (a^2 + b^2 + c^2 - 2ab - 2bc - 2ac) = 0.$$

The Descartes Equation

Proof.

First, we solve for d from the Descartes Equation to find that

$$2(a^2 + b^2 + c^2 + d^2) - (a + b + c + d)^2 = 0$$

$$d^2 - 2d(a + b + c) + (a^2 + b^2 + c^2 - 2ab - 2bc - 2ac) = 0.$$

The quadratic formula gives

The Descartes Equation

Proof.

First, we solve for d from the Descartes Equation to find that

$$2(a^2 + b^2 + c^2 + d^2) - (a + b + c + d)^2 = 0$$
$$d^2 - 2d(a + b + c) + (a^2 + b^2 + c^2 - 2ab - 2bc - 2ac) = 0.$$

The quadratic formula gives

$$d = (a + b + c)$$
$$\pm \frac{\sqrt{4(a + b + c)^2 - 4(a^2 + b^2 + c^2 - 2ab - 2bc - 2ac)}}{2}$$
$$= a + b + c \pm 2\sqrt{ab + bc + ca}.$$

The Descartes Equation

Proof.

First, we solve for d from the Descartes Equation to find that

$$2(a^2 + b^2 + c^2 + d^2) - (a + b + c + d)^2 = 0$$
$$d^2 - 2d(a + b + c) + (a^2 + b^2 + c^2 - 2ab - 2bc - 2ac) = 0.$$

The quadratic formula gives

$$d = (a + b + c)$$
$$\pm \frac{\sqrt{4(a + b + c)^2 - 4(a^2 + b^2 + c^2 - 2ab - 2bc - 2ac)}}{2}$$
$$= a + b + c \pm 2\sqrt{ab + bc + ca}.$$

Thus, there are two options for d . Their sum is $2(a + b + c)$.

Corollary

A natural number n has $2^{\omega(n)-1}$ sum-symmetric packings, where $\omega(n)$ is the number of distinct prime divisors of n .

Proof.

Because $n = -xy$ determines the sum-symmetric packing for coprime x and y , write $n = p_1^{e_1} p_2^{e_2} \cdots p_k^{e_k}$, so $\omega(n) = k$. For each prime power we can choose to put it as a factor of x or y , so there 2^k total factor pairs xy but we divide by two to account for symmetry. Thus, n has $2^k/2 = 2^{k-1} = 2^{\omega(n)-1}$ sum-symmetric packings. □

Extended Example

Sum-symmetric: $[-xy, x(x+y), y(x+y), (x+y)^2 - xy]$

Example: $20 = 2^2 \cdot 5$, with $\omega(20) = 2$ and $20 \not\equiv 2 \pmod{4}$, so $\delta_{20} = 0$.

Total number is

$$\frac{20}{4} \prod_{p|20} \left(1 - \frac{\chi_{-4}(p)}{p}\right) + 2^{\omega(20)-\delta_{20}-1}$$

$$= 5 \left(1 - \frac{\chi_{-4}(2)}{2}\right) \left(1 - \frac{\chi_{-4}(5)}{5}\right) + 2^{2-0-1}$$

$$= 5 \left(1 - \frac{0}{2}\right) \left(1 - \frac{1}{5}\right) + 2 = 5 \left(\frac{4}{5}\right) + 2 = 6.$$

I am incredibly grateful to Professor Katherine Stange and Dr. James Rickards for taking me under their wing over the previous summer's REU. Their mentorship and encouragement inspired me to pursue not only this honors thesis, but a math conference across the country. Under their guidance, I have learned just how fun math research can be! Working on this thesis has been one of the most fulfilling projects I have undertaken.

I am also thankful to the Honors committee for reviewing my thesis. Without them, the honors program would not be possible.

Thank You!
